解決方案

SeaDeep

A web-based, no-code platform

Connect

Easily ingest all plant data

Transform

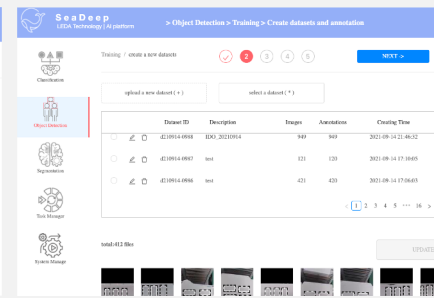

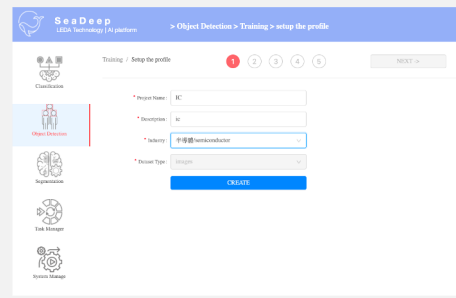

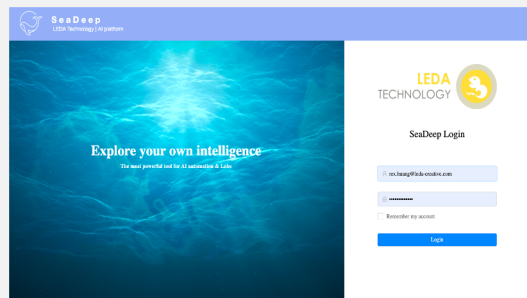

Automate data transformation

Analyze

Analyze transformed data with built-in apps without coding

Deploy

Deploy solutions to edge devices by just one click.

AIoT

Integrated with SeaDeep AI training platform

Simplified Integration

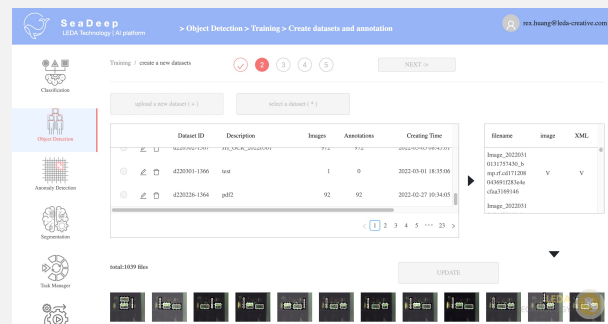

Neon smart cameras combine everything you need into all-in-one hardware solution.

Fast Deployment

Neon smart cameras support SeaDeep, LEDA's AI training platform so as to speed up the development process.

Data Health Check

Understand your data health helps you make informed decisions about how you process your data.

User Case

Contact Lens

Reports

Automated inspection, optimized with the Intel® Distribution of OpenVINO™ toolkit, leads to faster, more accurate results

"The ADLINK AI contact lens inspection solution, based on well-validated, cost-effective Intel® hardware and optimized with the Intel® Distribution of OpenVINO™ toolkit, offers contact lens manufacturers a reliable all-defect inspection solution with 95 percent accuracy."¹

—Tim Juan, Senior Director,
ADLINK Smart Factory Business Center

A clear advancement for machine vision

As demand for contact lenses grows, automating inspection processes is critical for manufacturers under pressure to increase throughput. Using ADLINK's AI machine vision system, optimized with the Intel® Distribution of OpenVINO™ toolkit, AI software partner LEDA Technology created easy-to-use contact lens inspection software that replaces human visual inspection. Using a smart inspection solution massively scales the number of lenses that can be inspected in a day.

The flexibility of the Intel Distribution of OpenVINO toolkit creates opportunities for software partners and manufacturers to develop tailored, smart solutions that solve unique customer challenges in the healthcare manufacturing industry.

Challenges: Bridging the gap between human and machine inspection

Inspecting contact lenses for manufacturing defects presents several unusual challenges. While most manufacturers can use a sample of products, contact lens manufacturers must inspect each individual lens. With 4,000 lenses inspected per day by each inspector, human visual inspection creates a production bottleneck with high rates of false discovery and missed detection.

Due to the transparency of contact lens material, machine vision-based inspection has been very challenging for the industry. Conventional machine vision automated optical inspection (AOI) relies on fixed geometric algorithms to discover defects, but acquiring quality images from high-transparency objects resulted in unacceptable inspection performance. Manufacturers seeking machine vision solutions want a faster way to accumulate data and train new algorithms, which has historically been a time-consuming process with impacts that result in increased operating expenses.

Solution: 50x faster inspections¹ with 3x improved accuracy²

LEDA Technology adopted ADLINK's AI machine vision technology to build a smart inspection solution. In addition to more accurately identifying lenses with manufacturing defects, the solution also collects data from inspection devices to train AI and iterate on inspection performance gains and maintains inspection logs for customer reference. LEDA Technology provides a reliable multi-defect-inspection solution, identifying defects including burrs, edges, particles, bubbles, scratches, and more.

LEDA Technology's AI contact lens inspection solution uses the well-validated EOS-i6000-M Series vision system, supporting a wide variety of deep learning applications. The system features a 9th Gen Intel® Core™ i7-9700E processor and four add-in accelerators based on Intel® Movidius™ Myriad™ X VPUs, optimized

New machine vision breakthrough - AI-enabled contact lens inspection guarantees defect-free transparent products

Press release Wednesday 12 February 2020

As the final step in the production process, inspection is of critical importance to the manufacturing industry. Manufacturers generally allot adequate staff resources to perform inspection for the purpose of safeguarding product quality. However, there is a limit to what people can do and human visual inspection may be error-prone.

To address the issue, LEDA Technology adopted ADLINK's machine vision system and built a smart inspection solution for use as part of a contact lens manufacturing process. According to LEDA Technology CEO Che-Hsian Huang, aside from quickly catching product defects through machine vision-based inspection, the solution can also collect data from individual inspection devices and conduct AI training to keep strengthening the inspection performance.

Starting out as a developer of image processing technologies, LEDA has been expanding into artificial intelligence (AI) technology research as smartization becomes a trend in manufacturing in recent years. It is working on solutions that capture and feed image data to the system to do further processing, the result of which then serves as the basis for making process improvements. LEDA currently focuses on technology development and system application for the manufacturing industry, including defect inspection of LED, metal work pieces and contact lenses. In particular, its solution used in the contact lens manufacturing process is a benchmark representative of LEDA's incredible achievement in AI-enabled machine vision.

The CEO said that consumer demand for contact lenses is on the rise for style and convenience reasons. To keep up with the increasing demand, manufacturers need to produce them at a rapid rate. As contact lenses are made from transparent materials, making machine vision-based inspection very challenging, inspection has generally been performed by humans. Furthermore, manufacturers conduct 100% full inspection on contact lenses as opposed to most other products for which sampling inspection is more common. Due to production in a large quantity and at a rapid rate in addition to 100% full inspection, inspectors have to visually check about 4,000 small contact lenses a day, which causes the rates of false discovery and missed detection to remain high. LEDA's solution can improve inspection performance for manufacturers with help from ADLINK's hardware platform and professional technical support.

According to LEDA CTO Si-Syuan Huang, to improve manufacturing system performance, instabilities on the production line need to be kept to a minimum so that data can be steadily generated and accurately tracked and then used to calibrate the production process for maximum benefits. Human visual inspection is the main cause of instability in the current manufacturing

- Improved data security and privacy of organizations through edge architecture

Organizations deploying edge CV to improve physical safety and security seek solutions that can detect objects (such as safety gear and heavy machinery), automate geofences and monitor remote sites. In this manner, organizations can use the CV edge to enforce safety protocols and geofences and monitor remote site access. Edge AI also drives industrial process automation, which improves product quality and production efficiency and throughput. Lastly, product improvement use cases can include a variety of products, ranging from computers to medical devices, to smart home appliances.

Use-Case Examples

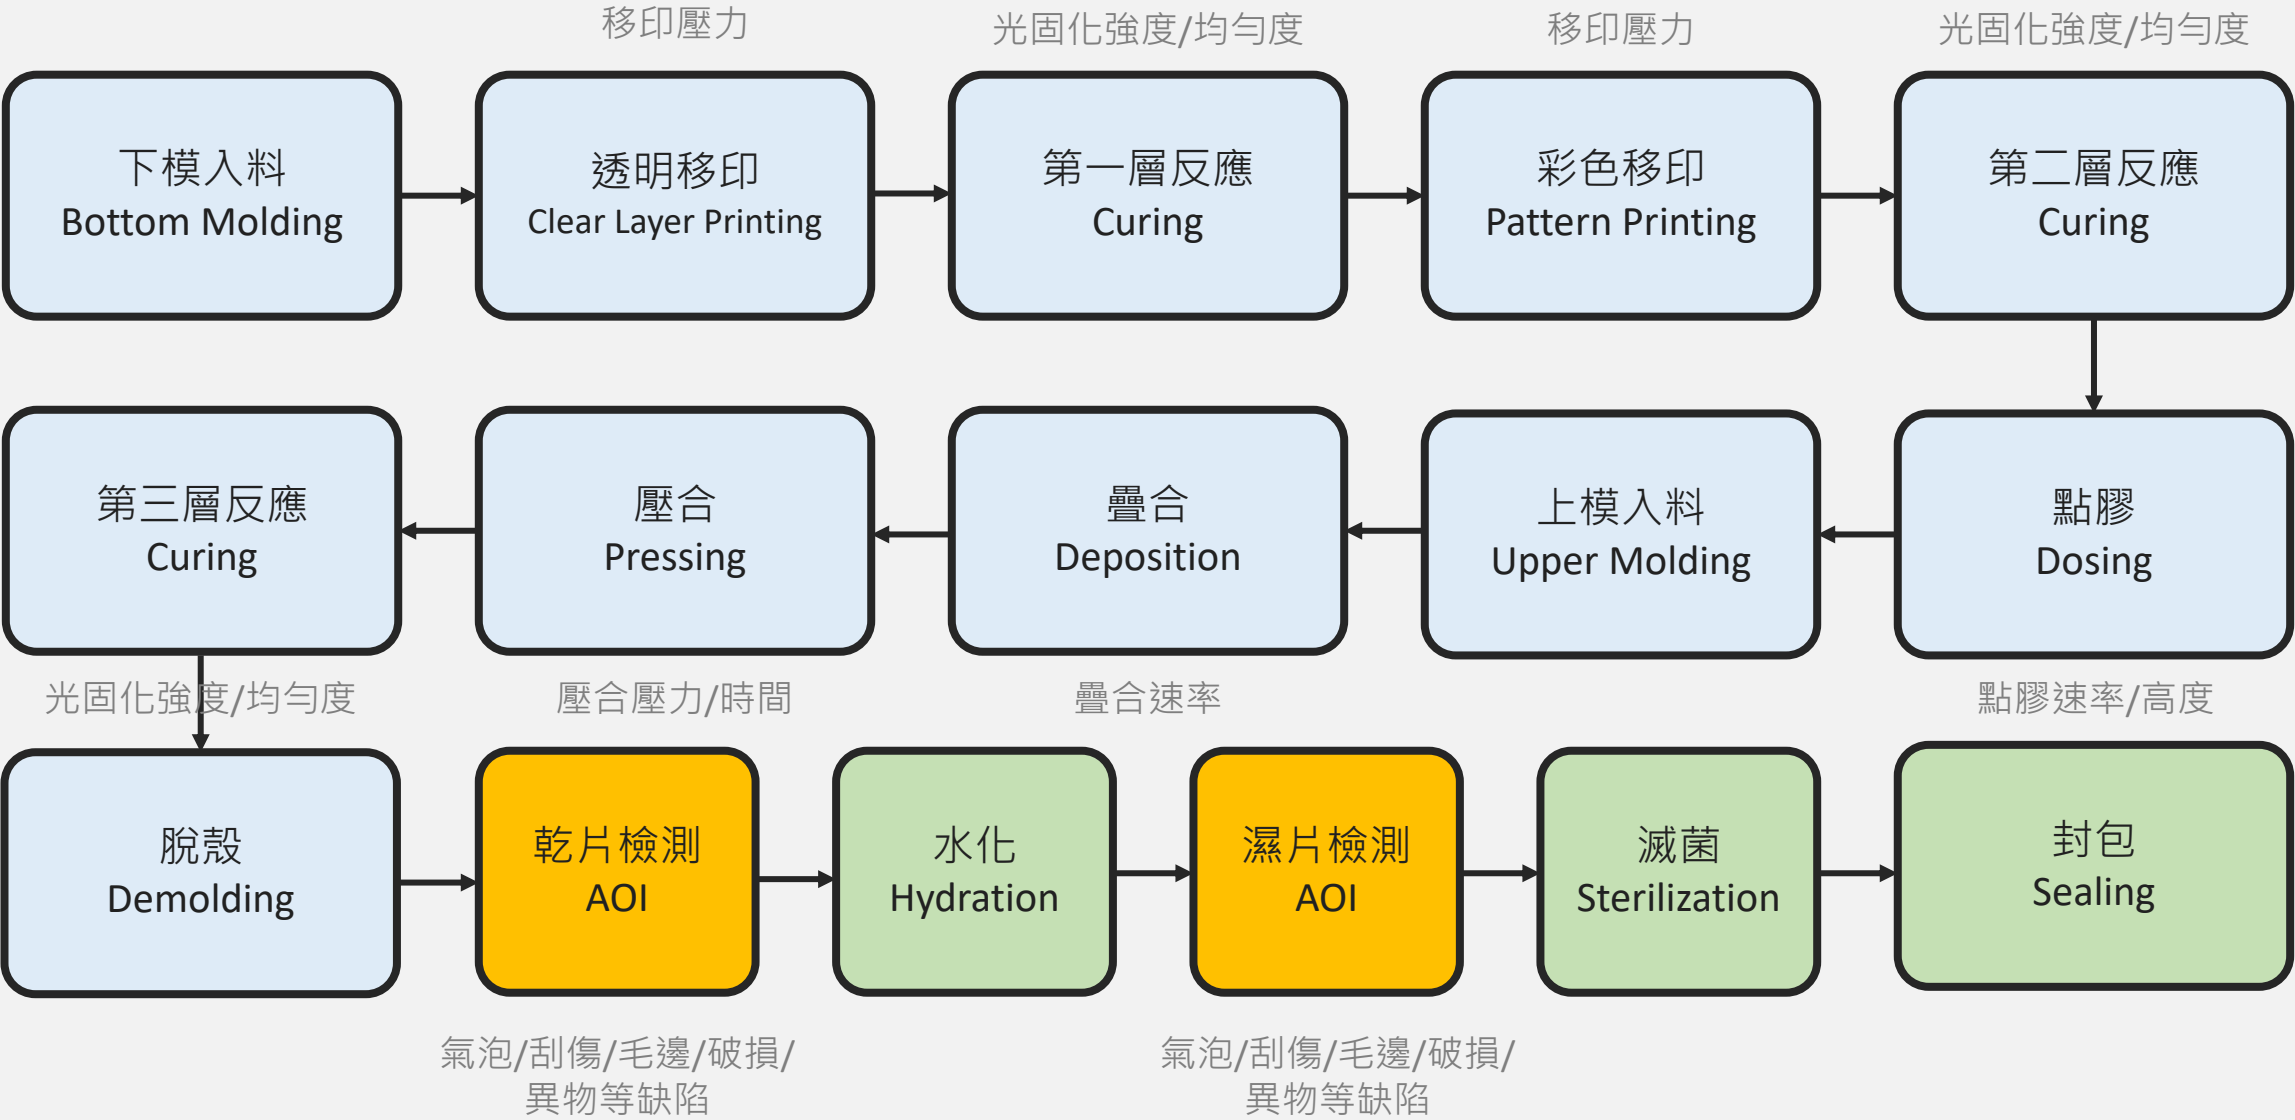

An example of edge AI improving quality management in manufacturing is Intel's use case with an undisclosed contact lens manufacturer in Taiwan. The goal of this implementation was to improve product throughput and quality by decreasing inspection time and increasing inspection accuracy. LEDA Technology partnered with Intel and ADLINK to build a smart inspection solution. On the hardware side, ADLINK's Machine Vision EOS-i6000-M Series features Intel accelerators (second-generation Movidius Myriad X VPU) and processors (ninth-generation Intel Core i7-9700E). On the software side, ADLINK worked with its ISV partner, LEDA Technology, for model training, using OpenVINO for model testing and deployment. Notably, this solution required the installation of high-resolution cameras along the production line.

In terms of results, product inspection time decreased from 20 to 30 seconds per unit to 0.4 seconds per unit, with a 95% accuracy rate compared to manual inspection. This increased inspection throughput by 50 times.

Edge-AI-enabled CV is also used to ensure operational excellence by improving employee physical safety and security. For example, a hardware manufacturer specializing in remote infrastructure systems is leveraging Chooch's offering for remote security. Chooch software is installed on the manufacturer's ruggedized device enabled with Ethernet radio, which is deployed in industrial environments and serves as a video aggregation point for existing security camera infrastructure. As of 1 August 2020, Chooch transitioned this client use case from a hybrid edge cloud to a full edge solution.

AI models are deployed remotely to the device. These models identify events of interest in video streams and alert end users, typically through an email or text message. Notably, this Ethernet radio is scheduled for a GPU-embedded upgrade, which will enable more AI models to run on the edge, as well as faster
